pyhf Core Developers

funcX Developer
We're high energy particle physicists
Goals of physics analysis at the LHC

- Search for new physics
- Make precision measurements
- Provide constraints on models through setting best limits

- All require **building statistical models** and **fitting models** to data to perform statistical inference
- Model complexity can be huge for complicated searches
- **Problem:** Time to fit can be **many hours**
- **pyhf Goal:** Empower analysts with fast fits and expressive models
pyhf: pure-Python HEP statistical models

- Pure Python implementation of ubiquitous high energy physics (HEP) statistical model specification for multi-bin histogram-based analysis
- Supports multiple computational backends and optimizers (defaults of NumPy and SciPy)
- JAX, TensorFlow, and PyTorch backends can leverage hardware acceleration (GPUs, TPUs) and automatic differentiation
- Possible to outperform traditional C++ implementations that are default in HEP
- Ways to learn more:
HPC facilities are more commonly available for use in HEP and provide an opportunity to efficiently perform statistical inference of LHC data.

Can pose problems with orchestration and efficient scheduling.

Want to leverage pyhf hardware accelerated backends at HPC sites for real analysis speedup:
  - Reduce fitting time from hours to minutes.

Idea: Deploy a pyhf based (fitting) Function as a Service to HPC centers.

Example use cases:
  - Large scale ensemble fits for statistical combinations.
  - Large dimensional scans of theory parameter space (e.g., Phenomenological Minimal Supersymmetric Standard Model scans).
  - Pseudo-experiment generation (“toys”).

Model that takes over an hour with traditional C++ framework fit in under 1 minute with pyhf on local GPU.
HPC facilities are more **commonly available** for use in HEP and provide an opportunity to **efficiently perform statistical inference** of LHC data.

- Can pose problems with orchestration and efficient scheduling.
- Want to leverage **`pyhf`** hardware accelerated backends at HPC sites for real analysis speedup.
  - Reduce fitting time from hours to minutes.
- **Idea**: Deploy a **`pyhf`** based **(fitting) Function as a Service** to HPC centers.
- **Example use cases**:
  - Large scale ensemble fits for statistical combinations.
  - Large dimensional scans of theory parameter space (e.g. Phenomenological Minimal Supersymmetric Standard Model scans).
  - Pseudo-experiment generation ("toys").

Integrate with **funcX** for fun and profit!
import json
import time
import pyhf
from funcx.sdk.client import FuncXClient
from pyhf.contrib.utils import download

def prepare_workspace(data, backend):
    pyhf.set_backend(backend)
    return pyhf.Workspace(data)

def infer_hypotest(workspace, metadata, patches, backend):
    pyhf.set_backend(backend)
    tick = time.time()
    model = workspace.model(...)
    data = workspace.data(model)
    test_poi = 1.0
    return {
        "metadata": metadata,
        "cls_obs": float(
            pyhf.infer.hypotest(test_poi, data, model, test_stat="qtilde")
        ),
        "fit-time": time.time() - tick,
    }

As the analyst user, define the functions that you want the funcX endpoint to execute.

These are run as individual jobs and so require all dependencies of the function to be defined inside the function.
Execution with funcX: Register and run functions

...  
def main(args):
...

    # Initialize funcX client
    fxc = FuncXClient()
    fxc.max_requests = 200
    with open("endpoint_id.txt") as endpoint_file:
        pyhf_endpoint = str(endpoint_file.read().rstrip())

    # register functions
    prepare_func = fxc.register_function(prepare_workspace)

    # execute background only workspace
    bkgonly_workspace = json.load(bkgonly_json)
    prepare_task = fxc.run(
        bkgonly_workspace, backend, endpoint_id=pyhf_endpoint, function_id=prepare_func
    )

    # retrieve function execution output
    workspace = None
    while not workspace:
        try:
            workspace = fxc.get_result(prepare_task)
        except Exception as excep:
            print(f"prepare: {excep}")
            sleep(10)

    ...

- With the user functions defined, they can then be registered with the funcX client locally
  - func.register_function(...)

- The local funcX client can then execute the request to the remote funcX endpoint, handling all communication and authentication required
  - func.run(...)

- While the jobs run on the remote HPC system, can make periodic requests for finished results
  - func.get_result(...)
  - Returning the output of the user defined functions
Execution with funcX: Scaling out jobs

... # register functions
infer_func = fx.register_function(infer_hypotest)
patchset = pyhf.PatchSet(json.load(patchset_json))

# execute patch fits across workers and retrieve them when done
n_patches = len(patchset.patches)
tasks = {}
for patch_idx in range(n_patches):
    patch = patchset.patches[patch_idx]
    task_id = fx.run(
        workspace,
        patch.metadata,
        [patch.patch],
        backend,
        endpoint_id=pyhf_endpoint,
        function_id=infer_func,
    )
tasks[patch.name] = {"id": task_id, "result": None}

while count_complete(tasks.values()) < n_patches:
    for task in tasks.keys():
        if not tasks[task]["result"]:  
            try:
                result = fx.get_result(tasks[task]["id"])
                tasks[task]["result"] = result
            except Exception as excp:
                print(f"inference: {excp}")
sleep(15)

...
Scaling of statistical inference

- **Example**: Fitting all 125 models from `pyhf` pallet for published ATLAS SUSY 1Lbb analysis
  - DOI: https://doi.org/10.17182/hepdata.90607
- **Wall time** under 2 minutes 30 seconds
  - Downloading of `pyhf` pallet from HEPData (submit machine)
  - Registering functions (submit machine)
  - Sending serialization to funcX endpoint (remote HPC)
  - funcX executing all jobs (remote HPC)
  - funcX retrieving finished job output (submit machine)
- **Time from submitting jobs to plot can be minutes!**
- **Deployments of funcX endpoints currently used for testing**
  - University of Chicago River HPC cluster (CPU)
  - NCSA Bluewaters (CPU)
  - XSEDE Expanse (GPU JAX)

```
feickert@ThinkPad-X1:~$ time python fit_analysis.py -c config/1Lbb.json
prepare: waiting-for-ep
prepare: waiting-for-ep

FaaS constraints and trade-offs

- The nature of FaaS that makes it highly scalable also leads to a problem for taking advantage of just-in-time (JIT) compiled functions
  - JIT is super helpful for performing pseudo-experiment generation
- To leverage JITed functions there needs to be **memory that is preserved across invocations** of that function
- FaaS: Each function call is self contained and **doesn't know about global state**
  - funcX endpoint listens on a queue and invokes functions
- Still need to know and tune funcX config to specifics of endpoint resource
  - No magic bullet when using HPC center batch

```python
In [1]: import jax.numpy as jnp
   ...: from jax import jit, random

In [2]: def selu(x, alpha=1.67, lmbda=1.05):
   ...:     return lmbda * jnp.where(x > 0, x, alpha * jnp.exp(x) - alpha)

In [3]: key = random.PRNGKey(0)
   ...: x = random.normal(key, (1000000,))

In [4]: %timeit selu(x)
850 µs ± 35.4 µs per loop (mean ± std. dev. of 7 runs, 1000 loops each)

In [5]: selu_jit = jit(selu)

In [6]: %timeit selu_jit(x)
17.2 µs ± 105 ns per loop (mean ± std. dev. of 7 runs, 100000 loops each)
```

50X speedup from JIT
Summary

- Through the combined use of the pure-Python libraries `funcX` and `pyhf`, demonstrated the ability to parallelize and accelerate statistical inference of physics analyses on HPC systems through a (fitting) FaaS solution.

- Without having to write any bespoke batch jobs, inference can be registered and executed by analysts with a client Python API that still achieves the large performance gains compared to single node execution that is a typical motivation of use of batch systems.

- Allows for transparently switching workflows between provider systems and from CPU to GPU environments.

- Not currently able to leverage benefits of JITed operations:
  - Looking for ways to bridge this.

- All code used public and open source on GitHub!
Thanks for listening!

Come talk with us!

www.scikit-hep.org/pyhf
Cloud service providers give an excellent Functions as a Service (FaaS) platform that can scale elastically.

Example: Running pyhf across 25 worker nodes on Google Cloud Platform.
- Results being plotted as they are streamed back.
- Fit of all signal model hypotheses in analysis takes 3 minutes!

Powerful resource, but in (academic) sciences experience is still growing.

"Pay for priority" model
- fast and reliable
- requires funding even with nice support from cloud providers.

(GIF sped up by 8x)
funcX endpoints on HPC: Config Example

Example Parsl HighThroughputExecutor config (from Parsl docs) that funcX extends

```python
from parsl.config import Config
from libsubmit.providers.local.local import Local
from parsl.executors import HighThroughputExecutor

config = Config(
    executors=[
        HighThroughputExecutor(
            label='local_htex',
            workers_per_node=2,
            provider=Local(
                min_blocks=1,
                init_blocks=1,
                max_blocks=2,
                nodes_per_block=1,
                parallelism=0.5
            )
        )
    ]
)
```

- 9 tasks to compute
- Tasks are allocated to the first block until its `task_capacity` (here 4 tasks) reached
- Task 5: First block full and
  \[
  \frac{5}{9} > \text{parallelism}
  \]
  so Parsl provisions a new block for executing the remaining tasks

- `block`: Basic unit of resources acquired from a provider
- `max_blocks`: Maximum number of blocks that can be active per executor
- `nodes_per_block`: Number of nodes requested per block
- `parallelism`: Ratio of task execution capacity to the sum of running tasks and available tasks
